

Mrs. Moore brings her six-month-old baby girl to see a pediatrician Dr. John. The child has been unwell for more than a week. The baby has a cough, runny nose, high temperature, and diarrhea. Mrs. Moore tells Dr. John that another doctor had seen the baby when she first became ill several days before and prescribed antibiotics and a liquid paracetamol. Mrs. Moore wants Dr. John's opinion because she worries about her child's condition. The doctor examines the baby's chest, throat and ears but finds no abnormality. The doctor tells Mrs. Moore to keep the child cool and continue with the paracetamol.
